

Remarks:

Numerous changes have been made to formatting to bring it into line with U.S. filing customs. No new matter has been added in making any of the changes.

Applicant believes that the application with Claims 1-24, 27-47, 50, and 51 as amended are patentable at this time. Accordingly, these claims remain pending following entry of this Preliminary Amendment, and the case with Claims 1-24, 27-47, 50, and 51 is believed to be in condition for allowance at this time. Applicant respectfully requests entry of this Amendment, and an early and favorable consideration of the claimed subject matter as amended is solicited. Should the Examiner believe that the prosecution of the application can be so expedited, the Examiner is requested to call Applicant's undersigned attorney at the number listed below.

Respectfully submitted:

MARKED-UP VERSION OF THE SPECIFICATION

VALVE PROSTHESIS

BACKGROUND OF THE INVENTION

5 | [0001] Field of the Invention -- The present invention relates to a valve prosthesis, particularly a stentless valve bioprosthesis. The present invention also relates to a stentless valve prosthesis for aortic valve and root replacement, particularly a stentless composite valve prosthesis.

10 | [0002] There are two principal classes of prosthetic subcoronary heart valve: the mechanical heart valve and the tissue heart valve. Mechanical heart valves are generally more durable but require patients to take anti-coagulants for the rest of their lives. Tissue heart valves in use are generally less durable; a high proportion may fail due to structural degeneration about seven years after implantation (depending on the age/activity of the recipient; see Turina et al (1993) *Circulation* 88(2), 775-781 for a review).

15 | [0003] Tissue valves may be divided into stented and stentless valves. Stented valves are preferred for their relative ease of insertion, but are not as flexible as stentless valves. Stents also increase the outer diameter of the valve and therefore reduce the inner valve diameter for a given aortic size by half a gauge size.

20 | [0004] Stentless tissue valves have great haemodynamic advantages over stented valves but unfortunately insertion of these valves in the subcoronary position is technically challenging (usually requiring two suture rows) and, probably for that reason, is only performed by very few surgeons around the world.

25 | [0005] Aortic valve and root replacement with a valved conduit is necessary when a patient's aortic wall is too weak/diseased to allow subcoronary valve

replacement (i.e. replacement of the valve leaflets with retention of the aortic wall (valve root)). Root valves consist of a valve mechanism inside a tube which is intended to replace part of the aorta, 5 including the aortic sinuses. In cases of severe aortic disease (aneurysm, dilated root, distorted root, small root and conditions such as Marfan's, replacement of the aortic root and part of the ascending aorta may become necessary.

10 | [0006] Most currently available valves achieve this by inserting a stented valved conduit between the aortic annulus (outflow) and ascending aorta (composite valve). As mentioned above, the presence of a stent reduces the size of the effective valve 15 area, thus compromising the left ventricular function.

15 | [0007] Dacron™ has previously been used. However, untreated Dacron™ is too porous and results in massive blood leakage. More recently, gel-sealed Dacron™ has also been used. Unfortunately, the gel dissolves when 20 brought into contact with fixation and preservation solutions such as glutaraldehyde or ethanol.

20 | [0008] Studies in the past have suggested that bovine pericardium might develop calcifications and eventually dilate if used for root replacement.

25 | [0009] Another currently available stentless valve substitute for root replacement consists of an actual porcine root. The arrangement of the coronary arteries on porcine roots is different from the human anatomy. As a result, modified surgical techniques such as rotating the valve or opening a new hole in 30 the root for satisfactory implantation of the right coronary artery is required. The most important disadvantage is the lack of large size availability.

35 | [0010] The muscular area of the porcine valve is not strong for sewing (after fixation) and needs to be covered by non-biological material to make it stronger for handling.

1 | [0011] The length of porcine valves is not suitable
2 | for wider replacement of the ascending aorta and hence
3 | will require the addition of another interposition
4 | graft.

5 | [0012] Another stentless root porcine bioprosthesis
6 | is an investigational stentless prosthesis with
7 | composite leaflets. Despite being stentless, the
8 | bioprosthesis is still bulky. The prosthesis is also
9 | available only in a limited range of sizes because of
10 | the limitations imposed by the size of available
11 | porcine valves (from which the prosthesis is
12 | constructed).

13 | [0013] Bioprostheses, including stented and
14 | stentless valves, are reviewed in, for example,
15 | *Cardiovascular Surgery: Cardiac valvular replacement*
16 | devices, residual problems and innovative
17 | investigative technologies *Surgical Technology*
18 | *International VII*, Jamieson & Lichtenstein and *25*
19 | *Years of Heart Valve Replacements in the United*
20 | *Kingdom, A guide to types models and MRI safety*,
21 | Maria-Benedicta Edwards, Heart Valve Registry,
22 | Hammersmith Hospital, 2000.

23 | [0014] WO00/00107 describes a tissue aortic
24 | stentless valve constructed entirely of biological
25 | tissue, in which leaflets are attached to an adjacent
26 | leaflet at a commissure region, using an arrangement
27 | of tissue reinforcing commissure posts and a separate
28 | reinforcing rim strip.

29 | [0015] WO01/05334 describes a flexible leaflet
30 | heart valve having leaflets with a scalloped and
31 | thickened free margin.

32 | [0016] US 5,713,953 describes a stentless valve
33 | prosthesis made from non-valve material, for example
34 | bovine pericardium, in which the outer sleeve and
35 | internal sheet which forms the valve flaps are each
36 | formed from an approximately rectangular or trapezoid

sheet. The internal sheet is subjected to a shaping (distortion) process before assembly into the valve.

SUMMARY OF THE INVENTION

[0017] We provide a heart valve prosthesis, which is considered to provide advantages in terms of durability and haemodynamic properties. In particular 5 we provide a stentless tissue heart valve, which retains advantages of present stentless heart valves, and is considered to provide further advantages in terms of durability, haemodynamic properties and ease of surgical insertion.

[0018] We also provide a stentless heart valve prosthesis suitable for replacement of the aortic root and also part of the ascending aorta made from non-10 valve material, for example pericardium. The prosthesis may be made in a wide range of sizes. Coronary button holes may be made during surgery to 15 suit the anatomy of the patient. In a preferred embodiment, the stentless annulus area of the valve is strong, scalloped and made especially for continuous suturing by extending the outer layer over the 20 leaflets layer. The less bulky annulus enlarges the effective orifice area.

[0019] A first aspect of the invention provides a heart valve prosthesis having a plurality of leaflets encircling a flow opening and of size to coapt to form 25 a valve, each leaflet having a free outflow edge at the outflow end of the leaflet, wherein the free outflow edge forms a convex (relative to the leaflet) curve in the plane of the leaflet.

[0020] A second aspect of the invention provides a 30 stentless heart valve prosthesis suitable for replacement of the aortic or pulmonary root comprising an outer wall and a plurality of leaflets positioned inside the outer wall, encircling a flow opening and of size to coapt to form a valve, wherein the outer 35 wall and leaflets are formed from material other than natural valve material.

| [0021] Preferably, the leaflets and outer wall are
5 formed from a sheet material or materials. More
preferably, the outer wall is formed from a biological
material (other than natural valve material), still
more preferably a biological material covered or
reinforced with a non-biological, biocompatible
material. The non-biological material may protect the
10 biological material against dilatation and/or
calcification and may also assist in retaining the
desired root shape, as discussed further below. Most
preferably, the outer wall is formed from pericardium
covered or reinforced on the outside with a woven
15 fabric, preferably woven polyester (PET), for example
Dacron™. The leaflets are preferably formed from a
biological material, for example pericardium. The
biological material leaflets are preferably without
covering or reinforcement with a non-biological,
20 biocompatible material. Thus, the outer wall may
comprise a layer of biological material and a layer of
a non-biological, biocompatible material.

| [0022] Preferably, each leaflet in the second
aspect of the invention has a free outflow edge at the
outflow end of the leaflet, wherein the free outflow
edge forms a convex (relative to the leaflet) curve in
25 the plane of the leaflet.

| [0023] The convex shape of the free edge of the
leaflet in both the first and second aspects of the
invention provides better coaptation than a straight
or concave upper edge, as used in other tissue heart
30 valves. The better coaption between the (preferably
three) leaflets reduces the stress transmitted to the
posts where they join and allows the valve to have a
lower profile (i.e. height of the leaflets from the
inflow edge to the outflow edge) than other valves,
35 and also a larger coaptation area. A recent paper
(Berk et al (2001) *J Heart Valve Dis* 10(1)) suggested
that the main stresses working on bioprosthetic heart

valves occur in the diastolic phase when the blood pushes back onto the top of the valve. The main stress is therefore exerted at the centre of the coaptation area rather than the posts. The convex
5 shape of the free (outflow) edge of the leaflet provides a larger coaptation area allowing the leaflets to stabilise each other when the valve is closed, reducing the stress transmitted to the posts during the diastolic phase.

10 | [0024] As will be apparent to those skilled in the art, the leaflets of the valve allow flow from the inflow to the outflow end of the valve when in the open position, but in the fully closed position the leaflets coapt to prevent flow back through the valve,
15 i.e. from the outflow end to the inflow end.

20 | [0025] A third aspect of the invention provides a method for forming a heart valve prosthesis comprising the step of forming a plurality of leaflets joined to encircle a flow passage and of a size to coapt to form a valve, wherein each leaflet has a free outflow edge at the outflow end of the leaflet, wherein the free outflow edge forms a convex (relative to the leaflet) curve in the plane of the leaflet.

25 | [0026] A fourth aspect of the invention provides a method for forming a stentless heart valve prosthesis suitable for replacement of the aortic root comprising the steps of forming an outer wall and a plurality of leaflets positioned inside the outer wall, encircling a flow opening and of size to coapt to form a valve, wherein the outer wall and leaflets are formed from material other than natural valve material.

30 | [0027] A fifth aspect of the invention provides a method for forming a heart valve prosthesis comprising the steps of: assembling the valve, by steps comprising forming a plurality of leaflets joined to encircle a flow passage and of a size to coapt to form a valve, and forming an outer sheet or wall joined to

the leaflets around an inflow end and along commissures formed where adjacent leaflets join; after assembly of at least the leaflets and outer sheet or wall of the valve; shaping the leaflets and/or outer sheet or wall to a desired shape; fixing the leaflets and/or outer sheet or wall of the valve in the desired shape.

5 | [0028] Preferably, the leaflets and/or outer sheet are shaped by inserting a shaping device into a pocket 10 formed by a leaflet and the outer sheet or wall (sinuses of valsalva). The shaping device is preferably a ball (preferably substantially spherical) formed of a resilient material, for example cotton wool. The shaping device may have the effect of 15 stretching portions of the leaflets and/or outer sheet into the desired shape.

15 | [0029] Preferably, the leaflets are shaped (and then fixed) into a form that aids their coaptation.

20 | [0030] Preferably, the outer sheet is also shaped to a desired shape and fixed in the desired shape. Still more preferably, the shaping of the outer sheet (i.e. the change in shape, the stretch or deviation/distortion relative to the initial 25 (unshaped) assembly) is in a portion of the outer sheet on the outflow side of the join between the outer sheet and the leaflets around the inflow end. Thus, the shaping is preferably in a portion of the outer sheet that corresponds to an aortic sinus in a natural aortic valve. Still more preferably, the 30 shaping is such that the outer sheet has a conformation resembling that of a natural aortic sinus, for example has the appearance of a bulge when viewed from the exterior of the valve.

35 | [0031] A sixth aspect of the invention provides a method for forming a stentless heart valve prosthesis comprising the steps of: forming a plurality of leaflets joined to encircle a flow passage and of a

size to coapt to form a valve; forming an outer sheet or wall joined to the leaflets around an inflow end and along commissures formed where adjacent leaflets join; wherein the join between the outer sheet or wall and the leaflets around the inflow end is at the periphery of the leaflets, and the outer sheet or wall extends by a distance between 0.3 and 4mm beyond the join with the leaflets at the inflow end, on the inflow side of the join, or (less preferably) the join between the outer sheet or wall and the leaflets around the inflow end is at the periphery of the outer sheet or wall, and the leaflet extends by a distance between 0.3 and 4mm beyond the join with the outer sheet or wall at the inflow end, on the inflow side of the join.

| [0032] It is preferred that the leaflets and/or outer sheet or wall (preferably both) are formed from material other than natural valve material. Still more preferably, the leaflets are formed from a sheet material, preferably a biological material, most preferably pericardium.

| [0033] Preferably the extension is between 1 and 2 mm. The extension provides a sewing ring by means of which the valve prosthesis may be attached to the heart or vessel tissue.

| [0034] It is preferred that the method of the sixth aspect of the invention further comprises the steps of after assembly of at least the leaflets and outer sheet or wall of the valve, shaping the leaflets and/or outer sheet or wall to a desired shape (preferably by inserting a shaping device into a pocket formed by a leaflet and the outer sheet or wall), and fixing the leaflets and/or outer sheet or wall of the valve in the desired shape. Preferences indicated in relation to the third to fifth aspects of the invention apply also to this aspect of the invention.

| [0035] The valve prosthesis may be suitable for use
as an aortic or pulmonary valve prosthesis, preferably
an aortic valve prosthesis.

5 | [0036] In relation to the third to sixth aspects of
the invention, it is strongly preferred that each
leaflet has a free outflow edge at the outflow end of
the leaflet which forms a convex (relative to the
leaflet) curve in the plane of the leaflet. This may
be beneficial for the reasons indicated above in
10 relation to the first and second aspects of the
invention.

15 | [0037] In relation to all aspects of the invention,
it is preferred that the inflow edge of each leaflet
is also convex (with respect to the leaflet) so that
the valve has a shape (slightly scalloped) which
complements the intended installation site, for
example the subcoronary position or in the aorta, for
example in place of part of the patient's aorta
comprising the aortic sinuses, as known to those
20 skilled in the art. Thus, it is preferred that the
valve has three curved portions that complement the
three aortic sinuses.

25 | [0038] A preferred leaflet shape is shown in Figure
1. Preferably, the leaflets form part of a single
piece of material, for example pericardium, as
discussed further below and shown in Figure 1. Thus,
the valve mechanism is preferably formed out of one
flat piece of material, for example pericardium, such
as bovine pericardium. The piece may have two or more
30 (preferably three) distinct but connected leaflet
regions, for example with convex inflow and outflow
edges for each leaflet.

35 | [0039] It is preferred that the curves of the
inflow and outflow leaflet edges are smooth convex
curves. For example, the inflow or outflow edge of
each leaflet may have substantially the shape of a
portion of the circumference of a circle. The radius

of the circle may be approximately equal to the maximum height of the leaflet i.e. the maximum distance between the inflow and outflow edge of the leaflet. Thus, if h is the maximum height of the leaflet, the radius of curvature (r) of the inflow or outflow edge (which need not be the same) of each leaflet may be $a \times h$, wherein a is between about 0.8 and 1.2, preferably between about 0.9 and 1.1, still more preferably between about 0.9 and 1.05, preferably about 1. The inflow or outflow edge may subtend an angle of between about 100° and 70° i.e. angle s or t in Figure 1 may be between about 100° and 70° , still more preferably between about 90° and 80° . The width of the leaflet (i.e. from one commissure-forming region to the opposite commissure-forming region) may be $b \times h$, wherein b is preferably between about 1.5 and 1, still more preferably between about 1.4 and 1.1, preferably between about 1.20 and 1.3, for example 1.24 to 1.27. Preferably, the commissure-forming edges are substantially parallel.

| **[0040]** Preferably, the sum of the widths of the leaflets is $\Pi \times$ the intended diameter of the valve. Thus, if the leaflets are formed from one piece of material, it is preferred that the width of the piece is $\Pi \times$ the intended diameter of the valve. For a valve with three leaflets (for example), each leaflet width is preferably $\Pi \times$ intended diameter/3.

| **[0041]** The outer wall (when present) of the second, fourth, fifth and sixth inventions may be formed from one or more layers of sheet material. Preferably, it comprises (or is formed from) a sheet of biological material, preferably pericardium (outer sheet) and a sheet of reinforcing material, preferably untreated (i.e. non gel-sealed) woven polyester (PET), for example Dacron™, forming an outer protective layer.

1 | [0042] The outer sheet for use in a heart valve
2 | prosthesis according, for example, to the first aspect
3 | of the present invention may preferably have a height
4 | (h₀) that is slightly greater than the maximum height
5 | h of the leaflets, for example between about 0.3 and
6 | 24 or 14mm, preferably between about 1 and 6mm greater
7 | than h, still more preferably about 3mm greater than
8 | h. The outer wall or sheet for use in a stentless
9 | heart valve prosthesis according to, for example, the
10 | second aspect of the present invention may preferably
11 | have a height (h₀) that is between 1 and 15 cm,
12 | preferably between 4 and 12 cm, still more preferably
13 | between about 8 and 10 cm greater than the maximum
14 | height h of the leaflets.

15 | [0043] The outer sheet in all aspects of the
16 | present invention preferably has a straight top (ie
17 | towards the outflow end of the valve) and a bottom
18 | edge (inflow end of the valve) that matches the shape
19 | of the leaflets. Thus, the bottom edge may have a
20 | scalloped appearance, having convex curved regions
21 | corresponding to the convex curved inflow edges of the
22 | leaflets. The outer sheet preferably has
23 | substantially the same (or slightly (for example 0.1
24 | to 5, preferably 0.5 to 2 mm) greater) width as the
25 | total width of the leaflets (i.e. w in Figure 1).
26 | Thus, w₀ in Figure 2 (which shows an outer sheet for
27 | use with the inner (leaflet) sheet of Figure 1) is
28 | preferably substantially the same as w in Figure 1.

30 | [0044] Exemplary leaflet dimensions and angles
31 | (which may be varied) are shown in Figure 7.

35 | [0045] The outer sheet is preferably formed from a
36 | single piece of material, but, much less preferably,
37 | may be formed from two or more pieces of material.
38 | The outer protective layer (when present) is
39 | preferably the same shape as the outer sheet and is
40 | likewise preferably formed from a single piece of
41 | material, or less preferably from two or more pieces

of material. The outer sheet and outer protective layer are of sufficient height to be useful in replacing at least part of the aorta in a patient.

5 | 10046 | The height indicated above for the outer sheet for use in a heart valve according to, for example, the first aspect of the present invention is preferred because it facilitates assembly of the valve, for example by providing protection for the leaflets during assembly of the valve, and facilitates 10 shaping of the valve by providing a pocket (in conjunction with a leaflet) into which a shaping device may be inserted, as described above. However, the outer sheet may have a lower height in the non-commisural regions, though this is not preferred. 15 Preferably, the outer sheet is of sufficient height in the non-commisural regions to retain a shaping device sufficiently firmly to shape/stretch the leaflets as required.

20 | 10047 | The material from which the leaflets and outer sheet are formed is preferably pericardium, for example bovine pericardium, or kangaroo, porcine, ovine or equine pericardium. Still more preferably, the pericardium (or other tissue) is treated to reduce the risk of calcification, for example by treatment 25 with ethanol (see, for example Vyavahare *et al* (1997) *Circulation* 95(2), 479-488). Ethanol treatment may result in reduction of lipid content and thereby reduce the risk of calcification. Pericardium is preferred as a result of its strength, flexibility and 30 durability. Bovine pericardium may be preferred because of its durability, availability and size (which is greater than, for example, pig pericardium). Equine pericardium is also suitable. Porcine pericardium is also suitable. It is generally thinner 35 than bovine pericardium and may be more suitable than bovine pericardium for smaller sized valves, for example valves intended for children.

1 | [0048] Other suitable materials for forming valve
2 | prostheses or parts thereof according to the invention, for example according to the first aspect
3 | of the invention, may include other biocompatible
4 | materials, which may be biological material or
5 | synthetic, for example synthetic polymers. WO00/08107
and US 5,713,953, for example, describe materials that
may be suitable. However, pericardium is considered
to be the most suitable material.

10 | [0049] When biological tissue is used, the
biological tissue is subjected to a cleaning operation
after harvesting, as known to those skilled in the
art. The tissue is examined and portions with
suitable properties, for example, strength and
15 | thickness, and which are sufficiently homogeneous, are
selected.

20 | [0050] The selected tissue is then subjected to
treatment operations intended to stabilise the elastic
and mechanical strength of the tissue, and to render
the tissue chemically inert with respect to blood.
These fixation or stabilisation operations may be
25 | performed by immersing the tissue in solutions of
glutaraldehydes with controlled pH. Treatment with
anticalcifying agents, for example ethanol may be
performed at the same time. The fixation operation
generally involves the formation of stable cross links
between the glutaraldehydes and the amino groups of
the proteins constituting the tissue.

30 | [0051] The treatment times may vary depending on
the characteristics of the tissue to be fixed and the
way in which the fixation is performed. The
concentration of the fixative may be varied during the
treatment process. For example, when glutaraldehyde
35 | is used, a prefixation phase may be performed with a
solution of glutaraldehyde with a concentration of
about 0.2%, which is increased in a final fixation
phase to a concentration of about 0.5%.

| [0052] In relation to aspects of the invention in
which the leaflets and/or outer sheet are shaped after
assembly of the leaflets and outer sheet, and are then
fixed in the desired shape, it is preferred that the
5 tissue forming the leaflets and/or outer sheet is not
completely fixed. It is preferred that the tissue,
for example pericardium, is partially fixed when
assembled into the valve, and is subsequently
subjected to a final fixation phase. The incompletely
10 fixed tissue retains characteristics of plastic
deformability which allow shaping operations to be
performed thereon. The finally fixed tissue has
different elastic characteristics such that, after a
possible deformation (for example during operation of
15 the valve, during which the leaflets move), the tissue
tends to return spontaneously to the conformation
assumed during fixation.

| [0053] Thus, in aspects of the invention in which
the leaflets and/or outer sheet are shaped after
20 assembly of the leaflets and outer sheet, and are then
fixed in the desired shape, it is preferred that the
leaflets and outer sheet are assembled from
pericardium which has not been fully fixed, and fixing
the leaflets and/or outer sheet of the valve in the
25 desired shape is performed by treatment with
glutaraldehyde.

| [0054] The outer protective layer (when present) is
formed from a material that is biocompatible and
resistant to fixation and preservation solutions such
30 as glutaraldehyde or ethanol. It should be capable of
assisting in retaining the root shape determined by
the outer sheet and/or of protecting the outer sheet
from calcification and/or rupture. The outer
protective layer may be porous, so long as the outer
35 sheet is not also porous. Thus, the outer protective
layer may be woven polyester (PET), for example
Dacron™ (or other suitable woven fabric) which has not

been gel-sealed, particularly when the outer sheet is formed from pericardium (preferably bovine pericardium).

5 | [0055] The joins between the leaflets and the outer sheet are preferably secured by means of sutures (stitching). The suture thread may be any suitable thread, as well known to those skilled in the art. Preferably, it is durable nylon or polyester thread. Suturing or stitching materials and techniques are 10 described in the Examples, and also, for example, in WO00/59379 and US 5,713,953. Moulding, gluing or welding may be used as an alternative (as mentioned in, for example, WO01/05334 or US 5,713,953), but is less preferred.

15 | [0056] In a preferred embodiment of, for example, the first aspect of the present invention, the valve may be assembled by stitching the leaflet sheet to the outer sheet, on the side which is to form the inside of the valve, for example as indicated in Figure 3a and described in Example 1. The commissures may be 20 formed by stitching through the outer sheet and the leaflet sheet. Reinforcement may be provided, for example in the form of strips of biocompatible material (for example a thin synthetic material, for 25 example PTFE (for example Teflon™) through which the stitching passes, as discussed further in Example 1. The edges of the leaflet and outer sheets are abutted and stitched to complete the encirclement of the flow passage. The inflow edges of the leaflets are sewn 30 onto the outer sheet (or, less preferably, vice versa). The leaflet sheet and outer sheet are preferably positioned so that the outer sheet extends by a distance between about 0.3 to 4mm (preferably 1 to 2 mm) beyond the inflow edge of the leaflet. The 35 join is preferably at the periphery of the leaflet sheet, so that the leaflet sheet does not extend beyond the join on the inflow side of the valve.

1 | [0057] The reinforcing material is preferably
2 | confined to the commissural regions (for example may
3 | extend for no more than 5, 4, 3, 2 or 1 mm on either
4 | side of a commissure). It is preferred that the width
5 | of the reinforcing strip is 1 to 4 mm, preferably 2
6 | mm. Preferably, it is of less than 3mm or 2mm thick
7 | in a plane perpendicular to the outer sheet; still
8 | more preferably, it is between 0.5 and 2mm thick. It
9 | is preferred that the reinforcing material does not
10 | increase the overall diameter of the valve prosthesis
11 | (i.e. the valve prosthesis fits through the same
12 | sizing hole in a size gauging device with or without
13 | the reinforcing strips). The reinforcement may be
14 | woven polyester (PET), for example Dacron™ (DuPont).
15 | [0058] In a preferred embodiment of, for example,
16 | the second aspect of the present invention, the valve
17 | may be assembled by stitching the leaflet sheet to the
18 | outer wall (outer sheet and outer protective layer),
19 | for example as indicated in Figure 3b and described in
20 | Example 2. The commissures may be formed by stitching
21 | through the outer protective layer, outer sheet and
22 | the leaflet sheet. The abutted edges of the outer
23 | sheet/outer protective layer are sewn together above
24 | the level of the top (outflow) edge of the leaflets to
25 | complete the encirclement of the flow passage. The
26 | inflow edges of the leaflets are sewn onto the outer
27 | sheet (or, less preferably, vice versa) and outer
28 | protective layer. The stitching may pass through the
29 | outer protective layer and the outer sheet. The
30 | leaflet sheet and outer sheet are preferably
31 | positioned so that the outer sheet extends by a
32 | distance between about 0.3 to 4mm (preferably 1 to 2
33 | mm) beyond the inflow edge of the leaflet. The join
34 | is preferably at the periphery of the leaflet sheet,
35 | so that the leaflet sheet does not extend beyond the
join on the inflow side of the valve.

1 | [0059] Alternatively, but less preferably, the join
2 | between the outer sheet and the leaflets around the
3 | inflow end is at the periphery of the outer sheet, and
4 | the leaflets extend by a distance between 0.3 and 4mm
5 | beyond the join with the outer sheet at the inflow
6 | end, on the inflow side of the join. In either
7 | arrangement, the extending material (preferably outer
8 | sheet or leaflet and outer protective layer when
9 | present) provides a sewing ring, by which the valve
10 | prosthesis may be secured in the desired position
11 | without having to sew through the leaflet and outer
12 | sheet on the outflow side of the leaflet-outer sheet
13 | join. It is preferred that the extending material is
14 | part of the outer sheet rather than the leaflet sheet,
15 | because this may minimise unwanted distortion of, or
16 | damage to, the leaflets on installing the valve
17 | prosthesis.

18 | [0060] It is preferred that, when used according
19 | to, for example, the first aspect of the present
20 | invention, after assembly of the valve and, if
21 | appropriate, after shaping and fixing steps are
22 | carried out, the outer sheet on the outflow side of
23 | the join between the outer sheet and the leaflets is
24 | trimmed close to the join (on the outflow side of the
25 | join). Preferably, the outer sheet is trimmed to
26 | within 2 mm, still more preferably 1 or 0.5 mm of the
27 | join, particularly the join at the inflow end of the
28 | valve (as opposed to the joins in the commissural
29 | regions). More of the outer sheet (preferably about 1
30 | to 2 mm) may be retained at the commissural regions,
31 | which may aid anchoring of the commissural regions at
32 | the site of insertion. The short trimming exposes the
33 | leaflets (Figure 4) and renders the valve suitable for
34 | insertion in a subcoronary position. The trimmed
35 | valve allows preservation of the aortic root
36 | structures (i.e. minimises obliteration of the aortic
37 | sinuses) and hence preservation of the dynamic

function of the aortic root structures. This may help in maintaining haemodynamic performance and maintaining low turbulence, and may thereby assist in prolonging the life of the prosthesis.

5 | [0061] The short trimming of the outer layer, just above the attachment of leaflets, has the advantage that it may be installed using a single suture line, thus simplifying installation and thereby shortening the time required (when compared with prostheses
10 | requiring double suture lines). This technique also completely eliminates obliteration of the aortic sinuses, i.e. provides for total integrity of aortic sinuses.

15 | [0062] When assembled from non-valve material, for example pericardium, the valves according to all aspects of the present invention may be made to any desired size. For example, the valve may be made to the following sizes: 17, 19, 21, 23, 25, 27 and 29mm, which corresponds to the range of normal human adult
20 | aortic inner diameters. A size 15 valve may be made, which may be used in children. Larger valves may be made, for example for use in large animals, for example horses. Valves of sizes suitable for use in other experimental animals, for example sheep, may
25 | also be made.

| [0063] A further aspect of the invention provides a valve obtained or obtainable by a method of the invention.

30 | [0064] A further aspect of the invention provides a stentless heart valve prosthesis comprising a plurality of leaflets joined to encircle a flow passage and of a size to coapt to form a valve, an outer sheet joined to the leaflets around an inflow end and along commissures formed where adjacent
35 | leaflets join, wherein the join between the outer sheet and the leaflets around the inflow end is at the periphery of the leaflets, and the outer sheet extends

by a distance between 0.3 and 4mm beyond the join with the leaflets at the inflow end, on the inflow side of the join, or the join between the outer sheet and the leaflets around the inflow end is at the periphery of the outer sheet, and the leaflets extend by a distance between 0.3 and 4mm beyond the join with the outer sheet at the inflow end, on the inflow side of the join.

5 | [0065] In relation to this aspect of the invention, and the valve obtained or obtainable by a method according to the third and subsequent aspects of the invention, it is preferred that the leaflets are shaped/stretched to a desired shape and fixed in the desired shape. The outer sheet may also be shaped/stretched into a desired shape and fixed in the desired shape, still more preferably a shape resembling that of a natural aortic sinus, for example having the appearance of a bulge when viewed from the exterior of the valve.

10 | [0066] It is preferred that the outer sheet is trimmed close to the join between the outer sheet and the leaflets on the outflow side of the join, as discussed above. This may be done prior to supply of the prosthesis to the user (surgeon) or may be done by 15 the surgeon prior to installation of the valve prosthesis in the patient. Preferably it is done prior to supply to the user; this may result in more consistent trimming. This trimming may result in loss of any shaping of the outer sheet, as discussed above; thus, such shaping is of less importance if the outer sheet is to be trimmed close to the outer sheet/leaflet join.

20 | [0067] A still further aspect of the invention provides a stentless heart valve prosthesis suitable for replacement of the aortic root comprising a plurality of leaflets joined to encircle a flow passage and of a size to coapt to form a valve, an

outer wall joined to the leaflets around an inflow end and along commissures formed where adjacent leaflets join, wherein the outer wall and leaflets are formed from material other than natural valve material,
5 wherein the join between the outer wall and the leaflets around the inflow end is at the periphery of the leaflets, and the outer wall extends by a distance between 0.3 and 4mm beyond the join with the leaflets at the inflow end, on the inflow side of the join, or
10 the join between the outer sheet and the leaflets around the inflow end is at the periphery of the outer sheet, and the leaflets extend by a distance between 0.3 and 4mm beyond the join with the outer wall at the inflow end, on the inflow side of the join.

15 | [0068] In relation to this aspect of the invention, it is preferred that the outer wall (outer sheet and outer protective layer) is shaped to a desired shape and fixed in the desired shape, still more preferably a shape resembling that of a natural aortic sinus, for
20 example having the appearance of a bulge when viewed from the exterior of the valve.

| [0069] The outer wall may be at the outflow end of the prosthesis. If the surgeon during the operation decides that a root replacement will be sufficient,
25 the tubular extension can be cut down to the size of a root valve. For example, the tube (outer wall) can be cut just above the level of the leaflet outflow edges. Alternatively, the outer wall may be further trimmed so that the valve may be installed in the subcoronary
30 position without replacement of any portion of the aorta, but this is not preferred.

| [0070] In relation to all preceding aspects of the invention, it is preferred that the valve has three leaflets. Thus, for example, it is preferred that a
35 sheet that forms the leaflets of the valve has regions providing three leaflets.

5 | [0071] In relation to the first, third and fifth aspects of the invention, it is preferred that the valve is stentless. It is preferred that the valve comprises an outer sheet joined to the leaflets around an inflow end and along commissures formed where adjacent leaflets join.

10 | [0072] It is preferred that the leaflets are formed from material other than natural valve material. Still more preferably, the leaflets are formed from a sheet material, as discussed above, yet more preferably a biological material, most preferably pericardium.

15 | [0073] A further aspect of the invention provides a valve prosthesis according to the invention for use in medicine.

20 | [0074] A further aspect of the invention provides the use of a valve prosthesis according to the invention in the manufacture of a medicament for the treatment of a patient in need of repair or replacement of a heart valve. Preferably, the heart valve in need of repair or replacement is the aortic valve. Optionally, the patient is in need of replacement of a portion of the aortic wall (i.e. a portion of the aortic root and optionally also 25 ascending aorta).

30 | [0075] The patient is preferably a human but may be a non-human animal, for example a horse.

35 | [0076] A further aspect of the invention provides a method for repairing a heart valve comprising the step of providing a valve prosthesis of the invention, and suturing the valve prosthesis to the heart or blood vessel tissue of the patient. The method optionally includes the step of replacing the valve and part of the wall of the blood vessel with the valve prosthesis of, for example, the second aspect of the invention. The method may comprise the step of trimming the outer

wall to the desired length, depending on the extent of aortic tissue to be replaced.

5 | [0077] As will be apparent to those skilled in the art, the valve prosthesis is sutured in place after any necessary removal of the diseased heart valve leaflets, and any calcified material from the site of installation of the prosthesis.

10 | [0078] A further aspect of the invention provides a method of repairing a heart valve comprising the steps of: (1) providing a valve prosthesis according to, for example, the first aspect of the invention, wherein the valve has an outer sheet; (2) if not already done, trimming the outer sheet close to the join between the outer sheet and the leaflets on the 15 | outflow side of the join; (3) suturing the valve prosthesis to the heart or blood vessel tissue of the patient with a single suture row. The suture is preferably continuous and the annulus of the valve is fortified with this technique in mind.

20 | [0079] Preferably, the heart valve prosthesis is stentless.

25 | [0080] Preferably, the outer sheet and/or leaflets (preferably both) is formed from material other than natural valve material. Preferences in relation to the trimming of the outer sheet are discussed in relation to earlier aspects of the invention. For example, it is preferred that the outer sheet is trimmed to within 0.5-1mm of the outer sheet/leaflet join. The outer sheet may be marked with guidelines 30 | for trimming and/or stitching.

35 | [0081] After annular suture the three commissures are fixed to the wall of the aorta incorporating the PTFE (for example Teflon™) strips using between 1-4 mm interrupted sutures for each commissure.

35 | [0082] The prosthesis may be used or supplied with a holder, as is known for existing valve prostheses.

| [0083] All documents referred to herein are, for
| the avoidance of doubt, hereby incorporated by
| reference.

5 | [0084] The invention is now described in more
| detail by reference to the following, non-limiting,
| Figures and Examples.

DESCRIPTION OF THE DRAWINGS

[0085] These and other advantages of the present invention are best understood with reference to the drawings, in which:

5 ~~Figure Legends~~

[0086] Figure 1- is an Example of a leaflet sheet providing three leaflets.

[0087] Figure 2- is an Example of an outer sheet suitable for use with the leaflet sheet of Figure 1.

10 [0088] Figure 3a- is an Assembly of the valve prosthesis according to, for example, the first aspect of the invention. The leaflet sheet is placed against the outer sheet. The outer sheet extends beyond the leaflet sheet at top and bottom. Reinforcing strips (1) (for example of a PTFE (for example Teflon™) material) are placed against the outer sheet on the opposite side to the leaflet sheet and aligned with the intended commissure regions. Double sutures (2) are made through the reinforcing strip, outer sheet 15 and leaflet sheet. A single suture (5) is made along the periphery of the leaflet sheet to join the leaflet sheet to the outer sheet. The "seam allowance" (3) provides a sewing ring for securing the valve on implantation. The sewing ring may be reinforced or 20 secured, for example with blanket stitch (4).

25 [0089] Figure 3b- is an Assembly of the valve prosthesis according to, for example, the second aspect of the invention. The leaflet sheet is placed against the outer sheet. The outer sheet extends beyond the leaflet sheet at top and bottom. An outer protective sheet is placed against the outer sheet on the opposite side to the leaflet sheet. Double sutures (2) are made through the outer protective sheet, outer sheet and leaflet sheet. A single suture 30 (5) is made along the periphery of the leaflet sheet to join the leaflet sheet to the outer sheet. The "seam allowance" (3) provides a sewing ring for 35

securing the valve on implantation. The sewing ring may be reinforced or secured, for example with blanket stitch (4).

5 **[0090]** Figure 4- is an ~~A~~assembled valve according to, for example, the first aspect of the invention after trimming- from a ~~P~~erspective (aortic) view and an outer view (laid open).

10 **[0091]** Figure 5- is a ~~V~~iew of an annulus of an assembled valve according to, for example, the first aspect of the invention (ventricular view). The leaflet/outer sheet join is visible, as is the reinforced sewing ring region and the reinforced commissures.

15 **[0092]** Figure 6- is an ~~A~~assembled valve according to, for example, the second aspect of the invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

Example 1: Subcoronary stentless valve prosthesis

5 [0097] This example describes a subcoronary stentless valve prosthesis which is a preferred embodiment of aspects of the invention, in particular the first and third aspects.

10 [0098] The heart valve prosthesis is made from sheets of bovine pericardium, a very strong and durable tissue. The pericardium sheets are preserved in ethanol (20 to 80%) which has recently been shown to dissolve fat residues, thus reducing the risk of calcification. The suture thread is made of durable nylon or polyester thread.

15 *Valve design*

The leaflets

20 [0099] The valve mechanism is formed out of one flat piece of bovine pericardium. The sheet of pericardium is cut into three distinct but connected leaflets with convex upper (outflow) and lower (inflow) edges (Figure 1). The convex outflow edges provide better coaptation than straight or concave outflow edges. This allows the valve to have a lower profile (i.e. height of leaflets) than a valve with straight or concave outflow edges. The shape of the leaflets also allows the leaflets to stabilise each other when the valve is closed, thus making them more resistant to the stress exerted during the diastolic phase and also resulting in less stress to the posts where the leaflets join.

Outer sheet

35 [0100] The sheet which forms the leaflets is sewn onto another, slightly higher flat sheet of bovine pericardium of the same width as the leaflet sheet (Figure 2). This outer sheet has a straight top (outflow) edge, about 1-3mm higher than the leaflet

sheet. The bottom (inflow) edge of the outer sheet is about 1-2 mm longer than the leaflet sheet, i.e. extends about 1-2mm beyond the inflow edge of the leaflet sheet.

5

Valve assembly

| [0101] To reinforce the posts (which form the commissures) and facilitate their attachment to the inside of the aortic wall on implantation, small strips of reinforcing material, for example PTFE (for example Teflon™) are placed onto the outside of the outer sheet at the position of the posts. The PTFE strips are somewhat shorter towards the annulus (for example 1 to 5 mm shorter) than the length of the posts so as not to interfere with the overall diameter of the valve (the finished valve should still fit through the correct hole in a size gauging device, i.e. the size that it would fit through in the absence of the strips). The strips extend between 1-2 mm beyond the attachment of commissures. Leaflet sheet, outer sheet and PTFE strips are then sewn together by two rows of continuous stitching at each of the three commissures/posts, with the abut edges of the sheets forming the third post.

25 | [0102] The scalloped bottom (inflow) edge of the leaflet sheet is then sewn onto the outer sheet using double sutured stitching, leaving a 1-2mm "seam allowance" on the outer sheet. This seam allowance forms a sewing ring, but retains the original scalloped shape of the bottom edge. Sewing along this sewing area (when installing the valve), rather than through the leaflet and outer sheet also has the benefit of leaving the leaflets undamaged and without unwanted distortion. For reinforcement purposes and 30 to keep the bottom edge of the outer sheet tidy the bottom edge is reinforced with suturing, for example using a blanket suture. The stitching may also

provide a guide for the surgeon, which may help to avoid piercing the leaflets. The single layer of pericardium tissue is strong enough to fasten the valve to the aortic wall.

5

Shaping and fixation

| [0103] Once the valve is assembled, cotton wool balls are packed tightly into the three pockets formed in the closed valve between the leaflets and the outer sheet (sinuses of valsalva). The cotton wool balls give the valve leaflets their characteristic shape and also cause three slight bulges in the outer sheet, mimicking the natural aortic sinuses. The valve is then fixed into this shape in glutaraldehyde.

| [0104] Finally, the outer sheet is cut closely around the sewing edges under a microscope, thus exposing the leaflets (Figure 4).

| [0105] The valve is fixed/preserved in a glutaraldehyde 0.4% buffered saline solution pH4.7 and supplied sterile in a glutaraldehyde 0.2% solution.

Using the valve

| [0106] This valve is designed for insertion into the subcoronary position following removal of a patient's diseased valve leaflets. Since all valve components are cut to size from flat sheets of pericardium, valves can be made to any size. The envisaged sizes are 17, 19, 21, 23, 25, 27 and 29mm (considering the diameter at the sewing annulus area, at the inflow area) which corresponds to the range of normal human adult aortic inner diameters. A size 15 valve is also possible, which could be used in children.

35 **Example 2: Root replacement stentless valve prosthesis**

| [0107] This example describes a root replacement stentless valve prosthesis which is a preferred embodiment of aspects of the invention, in particular the second and fourth aspects.

5 | [0108] The leaflets and outer sheet of the heart valve prosthesis are made from sheets of bovine pericardium, a very strong and durable tissue. The pericardium sheets are preserved in ethanol (20-80%) which has recently been shown to dissolve fat residues, thus reducing the risk of calcification.

10 | The suture thread is made of durable nylon or polyester thread.

| [0109] The outer protective sheet is formed from an untreated (i.e. non gel-sealed) woven polyester material (PET), for example Dacron™ (DuPont) in the form of a tube.

Valve design
The leaflets

20 As Example 1.

Outer sheet

| [0110] The outer sheet (onto which the leaflet sheet is sewn) is formed from a flat sheet of bovine pericardium of the same width as the leaflet sheet (Figure 2). This outer sheet has a straight top (outflow) edge, about 8 to 10 cm higher than the leaflet sheet. The bottom (inflow) edge of the outer sheet scalloped in the same fashion as the bottom edge of the leaflet sheet, and is about 1-2 mm longer than the leaflet sheet, i.e. extends about 1-2mm beyond the inflow edge of the leaflet sheet.

Outer protective layer

| [0111] The outer protective layer is made from a flat sheet of untreated woven polyester (PET), for example Dacron™ and is of substantially the same shape as the outer sheet.

Valve assembly

5 | [0112] Leaflet sheet, outer sheet and outer protective layer are sewn together by two rows of continuous stitches at each of the three commissures, with the abutted edges of the sheets forming the third commissure. The two edges of the extended outer sheet are sewn together from the top of the third commissure upwards (i.e. towards the outflow end) using 10 continuous double stitching.

15 | [0113] The scalloped bottom (inflow) edge of the leaflet sheet is then sewn onto the outer sheet using double sutured stitching, leaving a 1-2mm "seam allowance" on the outer sheet. This seam allowance forms a sewing ring, but retains the original scalloped shape of the bottom edge. Sewing along this sewing area (when installing the valve), rather than through the leaflet and outer sheet also has the benefit of leaving the leaflets undamaged and without 20 unwanted distortion. For reinforcement purposes and to keep the bottom edge of the outer sheet tidy the bottom edge is reinforced with suturing, for example using blanket suture. The stitching may also provide a guide for the surgeon, which may help to avoid 25 piercing the leaflets. The single layer of pericardium tissue is strong enough to fasten the valve to the aortic wall.

Shaping and fixation

30 | [0114] Once the valve is assembled, cotton wool balls are packed tightly into the three pockets formed in the closed valve between the leaflets and the outer sheet (sinuses of valsalva). The cotton wool balls give the valve leaflets their characteristic shape and 35 also cause three slight bulges in the outer sheet, mimicking the natural aortic sinuses. The valve is then fixed into this shape in glutaraldehyde.

5 | [0115] A few continuous circular stitches in the
sinuses of valsalva will keep outer and inner layers
(pericardium and woven polyester (PET), for example
Dacron™) together to facilitate the procedure for
making button holes for coronary implantation.

10 | [0116] The valve is fixed/preserved in a
glutaraldehyde 0.4% buffered saline solution pH4.7 and
supplied sterile in a glutaraldehyde 0.2% solution.

10 | *Using the valve*

15 | [0117] This valve has an extended outer tube of 8-
10 cm for use as an ascending aorta replacement. If
the surgeon during the operation decides that a root
replacement will be sufficient, the tubular extension
can be cut down to the size of a root valve. Since all
20 valve components are cut to size from flat sheets of
pericardium, valves can be made to any size. The
envisioned sizes are 17, 19, 21, 23, 25, 27 and 29mm
(considering the diameter at the sewing annulus area,
at the inflow area) which corresponds to the range of
normal human adult aortic inner diameters. A size 15
valve is also possible, which could be used in
children.

25 | *Testing the valves*

30 | [0118] The valves are tested to ensure that they
are suitable for clinical use, for example that they
conform to ISO 5840 standards.

35 | [0119] Materials are tested as known to those
skilled in the art. For example bovine pericardium
may be tested for biocompatibility using the AMES
test, and chromosome aberration, sensitization
(Magnusson/Kligman), intracutane reactivity and
haemocompatibility tests. Mechanical analysis may
include stress-strain analysis and shrinkage
temperature tests. The sutures used may be tested

mechanically (tension stress) and for biocompatibility (cytotoxicity tests).

5 | [0120] The valves may be subjected to mechanical and hydrodynamical testing according to standard protocols. For example, the valves may be tested over at least 200 million cycles. It may be evaluated *in vivo*, for example in juvenile sheep (see below). The sheep may be assessed for survival at 150 days and by blood analysis, echocardiogram analysis, as well as 10 angioplasty, necroscopy and pathology.

Experimental Results.

15 | [0121] A biological stentless aortic valve was implanted in the orthotopic position with coronary implantation in juvenile sheep. The animal model was selected for the following reasons: (1) The sheep model is an accepted and established method to evaluate the safety and preliminary efficacy of new or 20 | modified cardiac devices (ISO & FDA). (2) The size of sheep and the cardiac anatomy is comparable to humans and allows implantation of clinical size devices using standard surgical techniques.

25 | [0122] Twenty four stentless pericardium valves were implanted using 17-19 mm sizes of Imperial Pericardium Valves. Thirteen animals had surgical details or early deaths (maximum of 3 days survival). Animals identified as KHA-01 to 11 were considered long term survival - more than 6 days and maximum of 176 days.

30 | [0123] All animals underwent clinical examination before surgery. Rectal temperature, mucous membrane, skin integrity, lynnphonodi, lungs and heart auscultation, abdomen palpation, behavior, reflexes and vital functions were checked. All animals were 35 | considered healthy. All animals received anthelmintic drug and antclostridial vaccine obeying to a sanity

calendar for this specie. All animals received prophylactic antibiotics prior the surgery.

Results

5 | [0124] Study ID KHA 01: All animals underwent clinical examination before surgery. Rectal temperature, mucous membrane, skin integrity, lynnphonodi, lungs and heart auscultation, abdomen palpation, behavior, reflexes and vital functions were checked. All animals were considered healthy. All animals received anthelmintic drug and antclostridial vaccine obeying to a sanity calendar for this specie. All animals received prophylactic antibiotics prior the surgery.

15 | [0125] Study ID KHA 02: A 5-month-old, 32kg female sheep (ear tag number 1033BR) underwent stentless aortic valve replacement. A bioprostheses device (size 17mm) was implanted with no complications. The surgical procedure and anesthesia recovery was uneventful and throughout the long-term holding period, the animal remained health and blood sampling was obtained per protocol. The animal was found dead on the 50th post-operative day.

25 | [0126] Study ID KHA 03: A 4-month-old, 35kg neutered male sheep (ear tag number 940BR) underwent stentless aortic valve replacement. A bioprostheses device (size 17mm) was implanted with no complications. The surgical procedure and anesthesia recovery was uneventful and throughout the long-term holding period, the animal remained healthy and blood sampling was obtained per protocol. An angiogram was performed on the 169th post-operative day. The animal was heparanized and sacrificed and underwent a necropsy. Figures 8a-d show the results of echocardiography analysis for this study. The aortic valve shows a normal Echo aspect with no evidence of anatomical or functional (dysfunctional) alterations.

1 | [0127] Study ID KHA 04: A 4-month-old, 35kg
2 | neutered male sheep (ear tag number 943BR) underwent
3 | stentless aortic valve replacement. A bioprostheses
4 | device (size 19mm) was implanted with no
5 | complications. The surgical procedure and anesthesia
6 | recovery was uneventful and throughout the long-term
7 | holding period, the animal remained healthy and blood
8 | sampling was obtained per protocol. The animal was
9 | found dead on the 50th post-operative day.

10 | [0128] Study ID KHA 05: A 4-month-old, 30kg
11 | neutered male sheep (ear tag number 957BR) underwent
12 | stentless aortic valve replacement. A bioprostheses
13 | device (size 19mm) was implanted with no
14 | complications. The surgical procedure and anesthesia
15 | recovery was uneventful and throughout the long-term
16 | holding period, the animal remained healthy and blood
17 | sampling was obtained per protocol. The animal was
18 | found dead on the 8th post-operative day.

19 | [0129] Study ID KHA 06: A 4-month-old, 30kg
20 | neutered male sheep (ear tag number 958BR) underwent
21 | stentless aortic valve replacement. A bioprostheses
22 | device (size 17mm) was implanted with no
23 | complications. The surgical procedure and anesthesia
24 | recovery was uneventful and throughout the long-term
25 | holding period, the animal remained healthy and blood
26 | sampling was obtained per protocol. The animal was
27 | found dead on the 6th post-operative day.

28 | [0130] Study ID KHA 07: A 4-month-old, 30kg
29 | neutered male sheep (ear tag number 890BR) underwent
30 | stentless aortic valve replacement. A bioprostheses
31 | device (size 19mm) was implanted with no
32 | complications. The surgical procedure and anesthesia
33 | recovery was uneventful and throughout the long-term
34 | holding period, the animal remained healthy and blood
35 | sampling was obtained per protocol. The animal was
36 | found dead on the 13th post-operative day.

1 | [0131] Study ID KHA 08: A 5-month-old, 25kg female
2 | sheep (ear tag number 948BR) underwent stentless
3 | aortic valve replacement. A bioprostheses device
4 | (size 19mm) was implanted with no complications. The
5 | surgical procedure and anesthesia recovery was
6 | uneventful and throughout the long-term holding
7 | period, the animal remained healthy and blood sampling
8 | was obtained per protocol. The animal was found dead
9 | on the 89th post-operative day.

10 | [0132] Study ID KHA 09: A 4-month-old, 25kg female
11 | sheep (ear tag number 1165BR) underwent stentless
12 | aortic valve replacement. A bioprostheses device
13 | (size 19mm) was implanted with no complications. The
14 | surgical procedure and anesthesia recovery was
15 | uneventful and throughout the long-term holding
16 | period, the animal remained healthy and blood sampling
17 | was obtained per protocol. The animal was found dead
18 | on the 71st post-operative day.

19 | [0133] Study ID KHA 10: A 4-month-old, 27kg
20 | neutered male sheep (ear tag number 1170BR) underwent
21 | stentless aortic valve replacement. A bioprostheses
22 | device (size 19mm) was implanted with no
23 | complications. The surgical procedure and anesthesia
24 | recovery was uneventful and throughout the long-term
25 | holding period, the animal remained healthy and blood
26 | sampling was obtained per protocol. An angiogram was
27 | performed on the 176th post-operative day. A
28 | 4.95L/min cardiac output was recorded without
29 | transvalvular pressure gradient. The animal was
30 | heparanized and sacrificed and recorded a necropsy.
31 | Figures 9a to 9c show the results of echocardiography
32 | analysis for this study. Leaflets of the aortic valve
33 | show mild alteration, the left coronary cusp presents
34 | some degree of restriction of the movement without
35 | stenosis.

36 | [0134] Study ID KHA 11: A 6-month-old, 28kg
37 | neutered male sheep (ear tag number 857BR) underwent

stentless aortic valve replacement. A bioprostheses device (size 19mm) was implanted with no complications. The surgical procedure and anesthesia recovery was uneventful and throughout the long-term holding period, the animal remained healthy and blood sampling was obtained per protocol. The animal was found dead on the 134th post-operative day. Figures 10a to 10e show the results of the echocardiography analysis for this study. The aortic valve shows normal Echo aspects with no evidence of anatomical or functional alteration.

[0135] Although the foregoing description of the present invention has been shown and described with reference to particular embodiments and applications thereof, it has been presented for purposes of illustration and description and is not intended to be exhaustive or to limit the invention to the particular embodiments and applications disclosed. It will be apparent to those having ordinary skill in the art that a number of changes, modifications, variations, or alterations to the invention as described herein may be made, none of which depart from the spirit or scope of the present invention. The particular embodiments and applications were chosen and described to provide the best illustration of the principles of the invention and its practical application to thereby enable one of ordinary skill in the art to utilize the invention in various embodiments and with various modifications as are suited to the particular use contemplated. All such changes, modifications, variations, and alterations should therefore be seen as being within the scope of the present invention as determined by the appended claims when interpreted in accordance with the breadth to which they are fairly, legally, and equitably entitled.

MARKED-UP VERSION OF THE ABSTRACT

VALVE PROSTHESIS

ABSTRACT OF THE DISCLOSURE

A heart valve prosthesis having a plurality of 5 leaflets encircling a flow opening and of size to coapt to form a valve, each leaflet having a free outflow edge at the outflow end of the leaflet, wherein the free outflow edge forms a convex (relative to the leaflet) curve in the plane of the leaflet, and 10 methods for forming such a valve. A stentless heart valve prosthesis suitable for replacement of the aortic root comprising an outer wall and a plurality of leaflets positioned inside the outer wall, encircling a flow opening and of size to coapt to form 15 a valve, wherein the outer wall and leaflets are formed from material other than natural valve material, and methods of forming such a valve prosthesis.
